JOB MARKET PAPER

"Group Size Effect in Sequential Multi-Battle Contests: An Experiment Study", with Yichuan Cai

This paper presents the result of a laboratory experiment that investigates the group size effect in the sequential multi-battle contest. We first generalized Konrad and Kovenock's (2009) result to multi-player ($n \geq 2$). Then we conducted an n-player ($n = 3$ or 6) multi-battle experiment to compare the all-pay auction and the Tullock lottery side by side. When the number of contestants is increased in a sequential multi-battle contest, we get the following result: First, in battle 1, the boundary distribution is distorted in the all-pay auction, but only the no entry rate is increased in the Tullock lottery. Second, when the players are not in the lead, the dropout rate is higher with more players in the game. Third, even though the total number of battles has not increased significantly due to the increased number of players, more players are adopting the dormant-reenter strategy. Finally, increasing the number of contestants results in a higher total contest effort and a higher winner individual effort. In general, the theory in the Tullock lottery provides a more accurate prediction than in the all-pay auction.
